Abstract: Objective: Exenatide, albiglutide, dulaglutide, and semaglutide are once-weekly glucagon-like peptide receptor agonists (GLP-1 RAs), approved to treat type 2 diabetes mellitus (T2DM). However, there is limited evidence concerning safety levels of once-weekly GLP-1 RAs, including cardiovascular risks and rare events. The current meta-analysis was conducted to pool all relevant evidence regarding safety levels of once-weekly GLP-1 RAs. Methods: The current meta-analysis was conducted using PubMed, Embase, Cochrane Library, and the Website www.clinicaltrials.gov, aiming to identify all available trials with a duration of at least 24 weeks. For dichotomous variables, Mantel-Haenszel odds ratios (MH-OR) for incidence of major cardiovascular events (MACE), such as all-cause and cardiovascular mortality, pancreatic cancer, prostate cancer, and papillary thyroid cancer, were calculated. Cardiovascular risks were estimated according to mean differences in changes in HbA1c, body weights, blood pressure, heart rates, and lipid profiles. Results: Of the 41 included trials, 39 studies provided at least one event on MACE. Incidence of MACE was significantly reduced by once-weekly GLP-1 RAs, compared with the comparators group. Subgroup analyses suggested that a significant reduction was obtained, comparing once-weekly GLP-1 RAs and placebos (P < 0.001). Furthermore, a significant reduction was noted in all-cause mortality rates. Non-significant differences were observed in cardiovascular mortality rates, as well as incidence rates of pancreatic cancer, papillary thyroid cancer, and prostate cancer. Conclusion: Cardiovascular safety levels of once-weekly GLP-1 RAs were determined for patients with type 2 diabetes mellitus.

Keywords: GLP-1 analogue, cardiovascular disease, mortality, meta-analyses, type 2 diabetes mellitus

Introduction

Progressive β-cell failure and insulin resistance are main clinical features of type 2 diabetes mellitus, leading to time-consuming treatments. Hence, exogenous insulin therapy has gradually become the most common replacement therapy, helping people receive the glycemic goal [1]. In a previous study [2], however, GLP-1 RAs showed superior effects, compared to other oral antidiabetic drugs, concerning reduction of glycated hemoglobin (HbA1c, %). They significantly reduced the risk of hypoglycemia in patients. GLP-1 acts on islet β -cells in a glucose-dependent manner. It promotes the transcription of insulin genes and increases the biosynthesis and secretion of insulin. Moreover, it can stimulate the proliferation and differentiation of β -cells and inhibit the apoptosis of β -cells, thereby increasing the numbers of islet β -cells. This suppresses the secretion of glucagon, appetite, and ingestion, delaying gastric emptying [3-5]. These pharmacological actions help to reduce postprandial blood glucose, maintaining it at a constant level without hypoglycemia. Clinical trials have demonstrated that GLP-1 RAs can control glycemia, reducing risks of hypoglycemia and improving weight loss.

Data from several sources have identified a significantly better adherence in once-weekly GLP-1 RAs-treated patients diagnosed with type 2 diabetes mellitus, compared with oncedaily GLP-1 RAs-treated patients [6]. The appearance of once-weekly injections has offered a great convenience to patients with type 2 diabetes mellitus. Once-weekly GLP-1 RAs include exenatide, albiglutide, dulaglutide, and semaglutide. In January 2012, an exenatide susta-

ined-release microsphere formulation was approved by the Food and Drug Administration (FDA). It is the first long-acting GLP-1 formulation with only one injection per week, aiming to greatly improve the quality of lives of diabetic patients [7]. Dulaglutide is the third once-week-ly GLP-1 RAs after exenatide and albiglutide. Semaglutide was approved by the FDA in December 2017, as the newest GLP-1 RA [8].

Evidence has demonstrated that uncontrolled diabetes increases risks of cardiovascular diseases (CVD). A large-scale and long-term randomized trial showed that GLP-1 RAs reduced occurrence rates of major adverse cardiovascular events (MACE) [9]. However, cardiovascular safety data of once-weekly GLP-1 RAs is lacking. Therefore, in the current study, MACEs of once-weekly GLP-1 RAs were analyzed, aiming to assess the cardiovascular safety from available trials and short-term clinical trials with a meta-analysis. One area of concern with GLP-1 Ras is pancreatic safety [10]. Rare events seldom supported by evidence before, such as papillary thyroid cancer and prostate cancer, were also assessed. Cardiovascular and rare events safety of once-weekly GLP-1 Ras, including exenatide, albiglutide, dulaglutide, and semaglutide, in randomized controlled trials (RCTs) were assessed. They were compared with placebos or other active drugs in patients diagnosed with type 2 diabetes mellitus.

Materials and methods

The current meta-analysis was based on the criteria of PR-ISMA statement [11] and was registered on PROSPERO. The registration number is CRD-42019121315.

Search method and study selection

Relevant studies were drawn from PubMed, Embase, and the Cochrane Library using the search terms 'exenatide' OR 'dulaglutide' OR 'albiglutide' OR 'semaglutide'. Studies using these terms were collected from inception up to Dece-

mber 2018. In addition, some completed but unpublished studies were reviewed from the www.clinicaltrials.gov register.

A meta-analysis was performed, collecting all randomized clinical trials mainly comparing cardiovascular risks with once-weekly GLP-1 RAs treatment with placebos or other active drugs (oral antidiabetic drugs and/or insulin). All screened trials lasted at least 24 weeks and all patients enrolled were diagnosed with type 2 diabetes mellitus. Two reviewers, independently, screened the titles and abstracts of the remaining studies after removing duplicates. They then investigated eligible studies by viewing full texts. Trials enrolling non-diabetic, nonweekly GLP-1 RAs, other diseases, and GLP-1RAs were excluded. No reviews were published elsewhere. After these exclusions, 46 records remained, describing 41 studies. These were included in the current meta-analysis (Figure 1).

Data extraction

For each eligible study, relevant data were extracted, including trial design, details of inter-

Study	Clinical trials	Trial duration	Intervention	Comparator	Pati (ID	ents /C)	Background therapy	Total HbA1c	Total BMI

vention and control treatment, participant baseline characteristics, and prespecified outcomes on rare events.

MACE was the principal outcome, including cardiovascular deaths, strokes and acute myocardial infarction, and serious cardiovascular events (heart failure, angina pectoris, coronary artery disease, sinus bradycardia). Secondary outcomes included all-cause and cardiovascular mortality. This study also collected cardiovascular risk factors, including changes in HbA1c, changes in body weights, data on endpoint totals and HDL cholesterol and triglycerides, as well as systolic and diastolic blood pressure levels, as secondary outcomes. In addition, occurrence rates of pancreatic cancer, papillary thyroid cancer, and prostate cancer, as rare adverse events, were assessed.

Risk of bias assessment

Cochrane's collaboration risk of bias tool [12] was used to determine risk of selection bias (random sequence generation), selection bias (allocation concealment), performance bias (blinding of participants and personnel), detection bias (blinding of outcome assessment), attrition bias (incomplete outcome data), and reporting bias (selective reporting), as well as other biases.

Data synthesis and analyses

Assessing occurrence of MACE, all-cause and cardiovascular mortality, pancreatic cancer, prostate cancer, papillary thyroid cancer, and relative cardiovascular risk factors, the current study pooled estimates across all trials, comparing once-weekly GLP-1 RAs with placebos or other active drugs. Subgroup analyses were condcuted for different types of comparators or individual once-weekly GLP-1 RAs.

For dichotomous variables, such as incidence of MACE and all-cause cardiovascular mortality, as well as prevalence of pancreatic cancer, prostate cancer, and papillary thyroid cancer, the number of events and totals of the treatment group and control group were collected, respectively. Mantel-Haenszel odds ratios (MH-OR) with 95% confidence intervals were calculated by the software directly. Zero events were excluded. A fixed-effects model was applied because of low heterogeneity. For continuous variables, such as cardiovascular risk factors, the mean and standard deviation of the treatment group and control group were collected, respectively. The inverse variance method was used to calculate mean differences (MDs) with 95% confidence intervals and a random-effects model was applied. Heterogeneity was assessed via l² statistics, with values < 50% accredited [13]. Funnel plots and Begg's adjusted rank correlation tests were used to estimate publication bias [14]. A 0.05 significance level was performed in all analyses. Study results were combined using RevMan 5.3 and STATA 12.0.

Results

Study characteristics

The study selection process is shown in **Figure** 1. A total of 3,765 studies were searched, with 1,173 duplicates removed. The remaining 2,592 reports were screened across titles and abstracts. The broad search identified 211 potentially eligible papers, with 165 excluded. There were 31 with a shorter duration. MACE, which was the principal outcome variable, could not be yielded by these papers. A total of 46 records, describing 41 studies, were eligible for the current meta-analysis. Of these, 13, 12, 11, and 5 reported information on once weekly dulaglutide, exenatide, albiglutide, and semaglutide, respectively. In total, there were 49,902 patients included in all eligible studies, with 26,322 in once-weekly GLP-1 RA groups and 23,580 in comparator groups. Once-weekly GLP-1 RAs were compared against placebos (17 studies), insulin (10 studies), metformin (2 studies), sitagliptin (7 studies), glimepiride (2 studies), other daily GLP-1 RAs (9 studies), and pioglitazone (3 studies). GLP-1 RAs in each study were compared with two or more medications and placebos. Characteristics of these included studies are shown in Table 1 [15-61]. The duration of trials ranged from 24 weeks to 7.5 years. Mean trial duration, baseline HbA1c, and body mass indexes (BMI) of enrolled patients were 4.6 years, 8.0%, and 30.75 kg/m², respectively.

Risk of bias

Assessment of risk of bias is shown in **Figure 2**. Selection bias was reported in almost all published studies adequately. Only conference abstracts or parts of full texts were not described. A total of 15 studies were open trails with at

least one arm, while others were double-blind trails. In all studies, there was low risk of bias associated with incomplete outcome data. Funnel plots and Egger's tests showed no evidence of publication bias (P = 0.828).

MACE

Of the 41 studies, 39 studies provided at least one MACE. Cases of albiglutide (NCTO-1733758) [54] and semaglutide (NCT01930188) [57] were excluded because of the absence of MACE. Overall. once-weekly GLP-1 RAs showed a significant reduction in MACE, with an odds ratio of 0.87 (0.82 to 0.94, P < 0.001) versus comparators (Figure 3). It also showed low heterogeneity levels, with a value of $I^2 < 50\%$. The funnel plot (Figure 4) showed no significant publication bias.

According to subgroup analyses, once-weekly GLP-1 RAs were associated with a nonsignificant trend towards a reduction in the rate of MACE, compared to insulin and pioglitazone. The number of trials was 10 and 3 (P = 0.08 and 0.07). A significant reduction was performed between onceweekly GLP-1 RAs and placebos (P < 0.001). Details are shown in Figure 5. In placebocontrolled trials, only albiglutide produced a significant reduction, compared to placebos [MH-OR 0.80 (0.70-0.92), P < 0.01].

All-cause and cardiovascular mortality

A total of 22 studies provided data concerning all-cause mortality. Of the 14 studies included in the meta-analysis,

each study described at least one death. Compared with comparators, once-weekly GLP-1 RAs produced significant changes in all-cause mortality [MH-OR 0.90 (0.81-0.99), p = 0.03] (Figure 6). Furthermore, subgroup analyses sh-

owed significant changes, compared to placebos (7 trials). However, non-significant changes were shown, compared to sitagliptin (2 trials), insulin (2 trials), other daily GLP-1 RAs (3 trials), and metformin (1 trial) (values of OR (95% Cl) 0.59 (0.18-1.92), 0.68 (0.12-3.71), 1.36 (0.33-5.62), and 0.33 (0.01-8.12) and P = 0.38, 0.65, 0.67, and 0.50, respectively).

A total of 19 studies provided cardiovascular mortality data. Of the 6 studies included in the meta-analysis, each study described at least one death. No significant differences between once-weekly GLP-1 RAs and comparators were demonstrated [MH-OR 0.91 (0.80-1.03), P = 0.13].

Figure 5. Subgroup analyses for incidence rates of major cardiovascular events for each individual trial with at least once event, comparing onceweekly GLP-1 RAs with different comparator groups.

primary outcomes were performed in the current analysis. Pooled analyses showed a significant reduction in HbA1c between once-weekly GLP-1 RAs and comparators (P < 0.001). Onceweekly GLP-1 RAs produced a significant reduction, compared to placebos, insulin, sitagliptin, and glimepiride. Mean differences of changes in HbA1c were -1.04% (-1.21 to -0.88), -0.28% (-0.43 to -0.13), -0.51% (-0.73 to -0.29), and -0.36% (-0.54 to -0.19), respectively. *P*-values

were all less than 0.001 (**Table 2**). Conversely, no significant differences were produced, compared to metformin and pioglitazone. Compared with other daily GLP-1 RAs, a trend towards a reduction was shown in changes in HbA1c with once-weekly GLP-1 RAs (P = 0.08).

Body weights: Compared with comparators, pooled analyses showed a significant reduction in changes in body weights with once-weekly GLP-1 RAs. (P < 0.001). Weights changed by -1.36 kg (-2.09 to -0.63), compared to placebos, -2.53 kg (-3.58 to -1.48), compared to insulin, -1.19 kg (-2.03 to -0.35), compared to sitagliptin, -2.13 kg (-2.50 to -1.75), compared to glimepiride, and by -4.45 kg (-5.39 to -3.52). compared to pioglitazone. Only when compared to other daily GLP-1 Ras did mean differences of changes in body weights increase by 0.39 kg (-0.21 to 0.99). There were no significant changes in body weights, compared to metformin (Table 2).

Blood pressure: A total of 30 trials included in this analysis measured blood pressure changes. Mean differences of changes in blood pressure were analyzed between onceweekly GLP-1 RAs and placebos (11 trials), insulin (7 trials), metformin (2 trials), sitagliptin (6 trials), glimepiride (2 trials), other daily GLP-1 RAs

(7 trials), and pioglitazone (2 trials), respectively. Significant changes in endpoint systolic (SBP) and diastolic blood pressure (DBP) were noted (**Table 3**). Once-weekly GLP-1 RAs significantly reduced systolic blood pressure by -1.85 mmHg (-2.72 to -0.99), compared to placebos, and by -2.29 mmHg (-3.13 to -1.44), compared to insulin. When compared with other daily GLP-1 Ras, mean differences of changes in SBP increased by 0.45 mmHg (-0.60 to 1.50).

Figure 6. Frost plot showing all-cause mortality for each individual trial with at least one event.

Reduction in diastolic blood pressure levels was on the margin of statistical significance (P = 0.05). Only when compared with pioglitazone were significant changes noted.

Heart rate: Only 19 trials measured heart rate changes. Overall, once-weekly GLP-1 RAs produced significant increases, according to pooled analyses (P < 0.001). In these subgroups, there were no significant differences in the effects of metformin and other daily doses of GLP-1 RAs on heart rates in patients.

Lipid profiles: A total of 18 studies provided total cholesterol, HDL cholesterol, and triglycerides data. Data from included trials demonstrated significant changes in total and HDL cholesterol between once-weekly GLP-1 RAs and comparators. Changes in HDL cholesterol levels were on the edge of statistical significance (P = 0.05). Conversely, no significant changes in triglycerides were noted between once-weekly GLP-1 RAs and comparators (**Table 4**). Total cholesterol was significantly reduced, comparing placebos and sitagliptin. HDL cholesterol was significantly reduced, compared with metformin. Triglycerides were reduced significantly in pioglitazone only.

Pancreatic cancer, papillary thyroid cancer, and prostate cancer

Across all studies, 22 studies reported pancreatic cancer. Of the 16 studies included in the current meta-analysis, each study described at least one death. In these trials, 36 patients experienced pancreatic cancer in once-weekly GLP-1 RA groups, compared with 28 patients in comparator groups, showing non-significant differences between the two groups [MH-OR 1.20 (0.76-1.89, p = 0.44)] (Figure 7).

Only 7 studies reported papillary thyroid cancer. Of the 5 studies included in the meta-analysis, each described at least one death. Moreover, only 2 patients evolved into papillary thyroid cancer in the once-weekly GLP-1 RA groups, compared with 4 patients in the comparator groups. No significant differences were noted between the two groups [MH-OR 0.84 (0.23-3.10), P = 0.79] (Figure 8).

Prostate cancer was reported in 3 trials. Only 3 patients evolved into prostate cancer while receiving once-weekly GLP-1 Ras. No patients evolved into prostate cancer in the comparator group. Non-significant differences were noted between the two groups [MH-OR 2.39 (0.38-15.21), P = 0.36] (Figure 9).

Discussion

Clinical efficiency levels of once-weekly GLP-1 Ras, compared to placebos or other active antidiabetic agents, have been reported in many meta-analyses [62-65]. Once-weekly GLP-1 RAs have shown better effects on HbA1c, lowering and controlling glucose, compared to other antidiabetic agents. Most importantly, good patient adherence has been reported. However, cardiovascular and rare events are important areas that require concern. Prior studies [66, 67] have noted the importance of cardiovascular and rare events but did not report details. The current meta-analysis pooled most available trials showing the safety of

Table 3. Mean differences in changes in systolic and diastolicblood pressure and heart rates at the endpoint between GLP-1RA and placebo/active comparators

cardiovascular and rare events of once-weekly GLP-1 RAs on patients diagnosed with type 2 diabetes mellitus. Results indicated that onceweekly GLP-1 RAs showed superior cardiovascular safety, compared with several antidiabetic agents. A significant reduction of MACE incidence was demonstrated, compared to placebos. Compared with insulin and pioglitazone, once-weekly GLP-1 RAs showed a trend towards a reduction of MACE incidence. Differences between various weekly GLP-1 RAs were performed. In placebo-controlled trials, albiglutide was associated with a greater reduction of incidence of MACE. In placebo-controlled trials of dulaglutide, heterogeneity was reduced to less than 50% when removing a single trial (AWARD-10) [23]. Heterogeneity of exenatide trials was reduced from 49% to 2% if one trial was removed (EXSCEL) [39]. A major cause of death of type 2 diabetes mellitus, MACE was not shown to play an important role in cardiovascular mortality between the two groups. Drawing conclusions from the above results, once-weekly GLP-RAs have better cardiovascular safety for treatment of type 2 diabetes mellitus.

Significant reductions in HbA1c levels [68], blood pressure, lipid profiles, and body weights of these agents demonstrated that once-weekly GLP-1 RAs had prominent efficiency in reducing cardiovascular risks, compared to placebos, insulin, and sitagliptin. It is conceivable that adiposity is a cause of MACE and lower weight and systolic blood pressure levels can reduce cardiovascular risks [69]. However, increments of heart rates would be a contrast to others, as it might increase the risk of MACE and death. Thus, to some extent, once-weekly GLP-1 RAs provides effects, facilitating the reduction of cardiovascular risks. Rare events (pancreatic cancer, papillary thyroid cancer, and prostate cancer) were also analyzed for the two groups. There were no distinct differences between we-

ekly and daily GLP-1 RAs, except for better adherence and tolerance for weekly GLP-1 RAs.

Effects and safety levels of once-weekly GLP-1 RAs have been assessed in previous studies. However, these studies mainly paid attention to blood glucose control and major adverse reactions. Only a limited number of trials included assessment of exenatide, albiglutide, and dulaglutide. Hence, to the best of our knowledge, the current meta-analysis is the first to collect evidence from trials supporting all once-weekly GLP-1 RAs approved by the FDA, including the newest agent semaglutide. Additionally, this is the first analysis to focus on cardiovascular risks and rare events. This study also included three published large-scale clinical trials with MACE as the principal outcome (EXSCEL, SUSTAIN-6 [60] and Harmony Outcomes [61]), enlarging the sample size and increasing the credibility of results.

Table 4. Mean differences in changes in total andHDL-cholesterol and triglycerides between GLP-1 RAand placebo/active comparators

One major drawback to the current study was that most of the trials only published positive data. The paucity of negative results may lead to a higher heterogeneity and publication bias. The lack of relevant data could also lead to additional bias. Two included trials did not report incidence of MACE. Only half of the trials reported mortality. Furthermore, few trials assessed rare events. Low incidence leads to less credibility. Only one trial did not assess cardiovascular risk factors. Moreover, analyses of cardiovascular risk factors had a higher heterogeneity due to different treatment backgrounds, additive doses of agents, criteria of outcomes, inclusion and exclusion standards, and trial duration. Due to data deficiencies, sensitivity-analyses could not be conducted in most cases.

Another limitation of the current study was that most of the trials were short-term clinical trials. Although a limitation was set, demanding that the duration of intervention could not be less than 24 weeks, typical cardiovascular outcome studies require longer duration times. Furthermore, most studies did not use cardiovascular outcomes as their principal outcome measure. Thus, existing data was incomplete. More importantly, patients with type 2 diabetes mellitus analyses were associated with low cardiovascular risks. Some of them had no history of cardiovascular disease. Patients included in typical cardiovascular outcome studies are mostly high-risk patients. To create a more credible metaanalysis, more large-scale and long-term clinical trials, assessing cardiovascular outcomes, are necessary. The current study performed comparisons concerning different types of active oral antidiabetic agents, such as DPP-4 inhibitors, biguanides, sulfonylureas, thiazolidinediones (TZDs), and daily GLP-1 RAs. However, in this study, assessing efficacy and safety differences from weekly GLP-1 RAs, only one representative drug was selected for each type of oral hypoglycemic agent. Only liraglutide and exenatide BID were selected for GLP-1 RAs administered daily. Therefore, more medicines from different active oral agents are necessary, aiming to expand the scope of application of results.

In conclusion, once-weekly GLP-1 RAs may reduce cardiovascular risks for patients with

type 2 diabetes mellitus, to some extent. In this study, cardiovascular safety levels of this method were confirmed, compared with placebos or active antidiabetic agents. Furthermore, incidence rates of rare events were confirmed to be similar between once-weekly GLP-1RAs and comparators. Aiming to achieve more credible results, more large-scale and long-term trials should be implemented.
