**Abstract:** To explore the expression levels of EGFL6 in colorectal cancer and the association between EGFL6 and its clinicopathological parameters in patients. Immunohistochemistry assay was used to detect the expression levels of EGFL6 in cancer tissues of 42 colorectal cancer cases and corresponding adjacent normal tissues. The associations between protein expression levels of EGFL6 and the clinicopathological features, such as age, gender, smoking status, drinking status, TNM stage, Tumor T status, lymph node status, distant metastasis, and tumor diameter were also analyzed. We measured the plasma EGFL6 levels of colorectal cancer patients by using a commercial enzyme-linked immunosorbent assay. The positive rate of EGFL6 in cancer tissues was significantly higher than that of cancer-adjacent tissues (P < 0.05). Correlation was found between the protein expression of EGFL6 and the TNM stage (P < 0.05), the tumor T status (P < 0.05), distant metastasis (P < 0.05) and tumor diameter (P < 0.05). The plasma EGFL6 levels were significantly higher in patients with colorectal cancer than in healthy controls (P < 0.001). Moreover, plasma EGFL6 levels were significantly higher in the patients with higher TNM stage (P = 0.024), tumor T status (P = 0.021), distant metastasis (P < 0.001), and tumor diameter (P = 0.049). Therefore, these results demonstrated that EGFL6 expression was correlated with the genesis and development of colorectal cancer.

Keywords: Colorectal cancer, EGFL6, ELISA, clinicopathological characteristics

# Introduction

Colorectal cancer (CRC) is the third most frequently diagnosed cancer and the fourth most common cause of cancer-related deaths worldwide [1]. Approximately 1.36 million novel CRC cases and 694,000 mortalities are attributed to CRC annually worldwide [2]. Numerous risk factors for CRCinclude age, hereditary components, chronic intestinal inflammation, obesity, excessive intake of alcohol and red meat, smoking and lack of physical exercise [3-5]. Currently, surgery followed by radiotherapy and chemotherapy remains the primary therapeutic strategy for patients with CRC; however, 25%-30% of patients are diagnosed at advanced stages and are unsuitable for surgical resection [6]. Despite the advancement in comprehensive therapy, the long-term survival of CRC patients remains unsatisfactory [7]. The poor therapeutic outcome of patients with CRC is mainly due to local recurrence and distant metastases, particularly liver metastasis [8]. Therefore, a comprehensive understanding of the mechanisms underlying CRC onset and development is particularly urgent for the identification of novel therapeutic strategies for patients with this malignant tumor.

Tumor invasion and metastasis are related to a series of complex processes, including cell adhesion, migration, invasion, angiogenesis, and anchorage-independent growth [9-12]. The epidermal growth factor (EGF) repeat superfamily features a series of conserved cysteines and glycines positioned in a domain of 30 to 40 residues [13]. EGF-like proteins are characterized by their multiple EGF repeats [14]. EGF-like repeat family members are predominantly secreted as cell surface molecules, and are often involved in the regulation of the cell cycle, proliferation, and developmental processes [15, 16]. The binding of EGF-like proteins to their receptors triggers a wide range of biological functions, including proliferation, differentiation, apoptosis, adhesion, and migration. EGF

motif-containing molecules have been previously linked to the progression of various cancers [17, 18], and the expression of EGF-like domain 6 (EGFL6) in tumors suggests that it may also be linked to cancer [19-22].

EGFL6 has been shown to be expressed in fetal tissues and pancreatic, lung, ovarian and breast tumors [23, 24]. Since EGFL6 is expressed specifically in certain tumors but not in normal adult tissues, the EGFL6 gene product represents a potential marker of malignancy. However, the potential expression and role of EGFL6 in patients with colorectal cancer have yet to be elucidated. In this study, we investigated the association between the clini-

copathological characteristics and level of EGFL6 in patients with colorectal cancer.

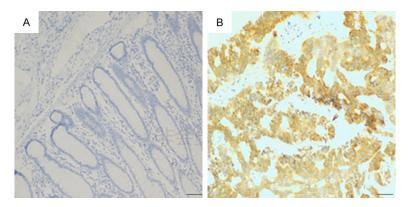

#### Materials and methods

Subjects and specimen collection

This study was approved by the Ethics Committee of Provincial Hospital Affiliated to Shandong University. Written informed consent was also provided by all patients enrolled in this study. In total, 42 pairs of CRC tissues and corresponding adjacent normal tissues were collected from CRC patients who were treated with surgical resection at the Provincial Hospital Affiliated to Shandong University between January 2011 and January 2017. Colorectal cancer was clinically staged at the time of diagnosis according to the TNM staging system of the American Joint Committee on Cancer (AJCC) Staging Manual, seventh edition. Medical information of the colorectal cancer patients including TNM clinical staging, primary tumor size, lymph node involvement, and histological grade was obtained from their medical records. Whole blood samples were collected from the patients and placed in tubes containing ethylene diamine tetraacetic acid. After immediate centrifugation at 3000 rpm, the supernatants were stored at -80°C.

# Immunohistochemical assay

The samples of cancer tissues and adjacent tissues were incised into paraffin sections with a diameter of 4 µm. Histological sections were first soaked into dimethylbenzene for 10 min, followed by dehydrated alcohol for 5 min, and then in succession in the following alcohol solutions for 5 min each for dewaxing with 95%, 80%, and 75% alcohol. After washing with distilled water, tissue peroxidase was blocked with 3.0% hydrogen peroxide in methanol for 15 min at room temperature. For antigen retrieval using citric acid buffer, the slides were heated at 120°C for 20 min and then cooled for 45 min at room temperature. After washing, the slides were incubated with primary mouse monoclonal antibodies against EGFL6 overnight at 4°C. The slides were washed with PBS, EGFL6 stained slides were incubated with biotinylated anti-mouse IgG (Histofine Simplestain Max PO; Nichirei, Tokyo, Japan) as second antibody for 1 h at room temperature. The slides were washed with PBS again and then incubated with horse-

**Figure 1.** EGFL6 expression in colorectal cancer tissue and normal intestinal tissues by immunohistochemistry. A. EGFL6 negative expression in normal intestinal tissues, ×400; B. EGFL6 positive expression in colorectal cancer tissues, ×400.

radish peroxidase-conjugated streptavidin (Histofine SAB-PO; Nichirei, Tokyo, Japan) for 30 min at room temperature. The immune reaction was demonstrated with DAB. The sections were then counterstained with Meyer's hematoxylin, dehydrated, and mounted.

# Quantitative analysis of plasma EGFL6 level

The plasma EGFL6 concentration was determined quantitatively using an enzyme-linked immunosorbent assay (ELISA). One hundred microliters of plasma sample (100-fold dilution), standard control sample, and internal quality control were placed into microtiter plates coated with a monoclonal antibody against EGFL6 and incubated for 2 h at room temperature on a horizontal orbital shaker at 200 rpm. The absorbance was measured at 450 nm by using a microtest plate spectrophotometer (BioTek Instruments, Vemont, USA). EGFL6 levels were quantified with a calibration curve using human EGFL6 as the standard.

## Statistical analysis

All analyses were performed using SPSS version 19.0 statistical software (SPSS Inc., Chicago, IL, USA). The demographic data are presented as number (%) and mean  $\pm$  standard deviation (SD). Significances of differences between means were calculated using Student's t-test. In addition, gender, smoking status and drinking status were analyzed using the  $\chi^2$  test. A p value < 0.05 was considered significant.

## Results

#### Patient characteristics

Forty-two patients with colorectal cancer were included in the analysis. **Table 1** presents the demographic data, and shows that 81% of the patients were smokers and 54.8% consumed alcohol. The TNM stage, Tumor T status, Lymph node status, Tumor diameter and distant metastasis of the patients are also shown in **Table 1**.

# Expression of EGFL6

EGFL6 was primarily expressed in the cytoplasm and cell membrane with yellow-brown granules. EGFL6 positive expression rate was significantly higher in cancer tissues than that in adjacent normal tissues (P < 0.01, Figure 1).

Correlation between EGFL6 expression and patients' clinicopathological features

Correlation was found between the protein expression of EGFL6 and the TNM stage (P < 0.05), the Tumor T status (P < 0.05), distant metastasis (P < 0.05) and tumor diameter (P < 0.05). It was not correlated with patient's age (P > 0.05), gender (P > 0.05), smoking status (P > 0.05), drinking status (P > 0.05) and lymph node status (P > 0.05) in **Table 2**.

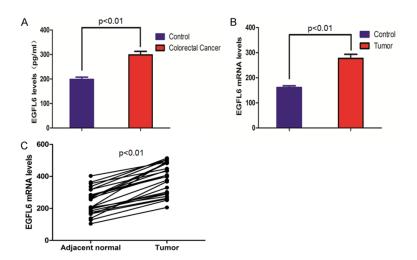

Correlation between plasma EGFL6 levels and clinicopathological characteristics of the patients

The mean plasma EGFL6 level was significantly higher in patients with colorectal cancer than in controls (298.67  $\pm$  94.64 pg/mL vs 198.09  $\pm$  54.16 pg/mL; P < 0.001) (**Figure 2A**). To verify our findings, TCGA colorectal cancer database was used in this study. The EGFL6 mRNA levels of colorectal cancer and normal tissues were evaluated. **Figure 2B** shows the EGFL6 mRNA levels were also significantly higher in patients with colorectal cancer tissues than in normal tissues. Moreover, the EGFL6 expression was also significantly increased in cancer tissue compared with that in the normal parts in colorectal cancer of the TCGA database (**Figure 2C**).

**Figure 2.** ELISA-determined plasma EGFL6 level of colorectal cancer patients. A. EGFL6 levels were compared according to normal control and colorectal

cancer patients. B. EGFL6 mRNA expressions were compared according to normal tissue and colorectal cancer patient tissues from the TCGA database. C. Relative expression of EGFL6 in 24 pairs of colorectal tumor tissues and their corresponding adjacent non-cancerous tissues.

The relationships between plasma EGFL6 levels and various clinicopathologic parameters of the patients are summarized in Table 3. Plasma levels of EGFL6 protein were not correlated with age, gender, smoking status, drinking status, and lymph node metastasis. However, they were significantly higher in patients with higher TNM stage (stage III + stage IV; P = 0.024), advanced Tumor T status (T3 + T4; P = 0.021), distant metastasis (M1; P = 0.000) and larger tumor diameter (> 5; P < 0.001). Detailed comparisons of plasma EGFL6 levels between the patients with different disease severity are illustrated in Figure 3. With regards to TNM stage, the levels of EGFL6 were significantly higher in the patients with stage IV (332.83 pg/mL) compared to those with an early stage (stage I: 274.22 pg/mL) (Figure 3). The levels of EGFL6 were significantly higher in the patients with advanced tumor T status (T4: 347.73 pg/mL) compared to those with early T status (T1: 273.67 pg/mL and T2: 286.64 pg/mL; P =0.004 and P = 0.020) (Figure 4).

# Discussion

We investigated the levels of EGFL6 in colorectal cancer patients, and found that levels of EGFL6 were correlated with TNM stage, tumor T status,

distant metastasis, and tumor diameter. EGFL6 protein levels were significantly higher in patients with higher TNM stage (stage III + stage IV; P = 0.024), advanced tumor T status (T3 + T4; P = 0.021), distant metastasis (M1; P = 0.000) and tumor diameter (> 5; P = 0.000). Previous reports have shown that tumor invasion and metastasis are related to cell adhesion, migration, invasion, and angiogenesis [25-30]. In addition, the EGFL6 protein has been reported to induce cell migration of endothelial cells [31-35]. These findings suggested that EGFL6 may promote colorectal cancer tumor invasion and metastasis by promoting cell migration and angiogenesis. Our results also suggest that EGFL6 may play an important role in the carcinogenesis of colorectal cancer.

Several EGF-like superfamily members have been identified, including EGFL2, EGFL3, EGFL5, EGFL6, EGFL7, EGFL8, and EGFL9. EGFL2, EGFL5 and EGFL9 contain transmembrane domains, however EGFL3, EGFL6, EGFL7 and EGFL8 lack transmembrane domains and are secreted as proteins. The EGFL6 gene maps to the human Xp22 chromosome and encodes a secreted protein containing multiple EGF repeat motifs, which is highly expressed in certain tumors and fetal tissues, suggesting a role as a growth factor [34, 36].

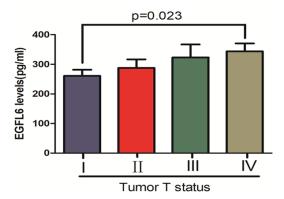

Previous studies have reported that the EGFL6 protein induces migration and angiogenesis of endothelial cells, but that endothelial cells themselves do not express EGFL6. Several signaling pathways during angiogenesis have been reported to be potentially activated, such as the integrin/FAK-mediated pathway, MAPK pathway, and the PIK3/Akt pathway [37, 38]. Chim et al. reported that extracellular signal-regulated kinase (ERK) is activated by the EGFL6 protein, and that inhibi-

tion of the ERK signaling pathway blocks EGFL6-induced ERK activation and endothelial cell migration. They further validated that EGFL6 promotes endothelial cell migration and angiogenesis via activation of the ERK pathway.

In addition to colorectal cancer, the overexpression of plasma EGFL6 has been observed in several tumors including brain, lung, ovarian, and breast tumors, but generally not in normal adult tissues [39-41]. EGFL6 has also been proposed to be a new target for diagnostic and therapeutic interventions in patients with breast cancer, which shows promise for new areas of basic research in tumor biology [41]. Combined with our results, the plasma level of

**Figure 3.** EGFL6 levels were compared according to stage. The levels of EGFL6 were significantly higher in patients with stage III (393.84 pg/ml) compared to those with early stage status (I: 273.64 pg/ml and II: 241.53 pg/ml; P = 0.028 and P = 0.020).

**Figure 4.** EGFL6 levels were compared according to T status. The levels of EGFL6 were significantly higher in patients with advanced tumor T status (T4: 343.68 pg/ml) compared to those with early T status (T1: 260.76 pg/ml; P = 0.023).

the EGFL6 protein appears to be a likely candidate biomarker for various human cancers.

To the best of our knowledge, this is the first report to examine the association between EGFL6 level and clinicopathologic characteristics for patients with colorectal cancer with regards to the possible application of this molecule as a tumor marker. We suggest that EGFL6 may play an important role in the carcinogenesis of colorectal cancer.

In summary, we found that a substantial increase in the plasma level of EGFL6 by ELISA is useful to assess disease progression, especially in patients with colorectal cancer with an advanced T status, higher TNM stage, longer distant metastasis and larger tumor diameter.

As a secreted protein, EGFL6 may not only play an important role in the carcinogenesis of colorectal cancer, but also find clinical applications as a biomarker for disease diagnosis and in planning therapy for colorectal cancer.
